The ESC/Java2 tool

Structure of ESC/Java2

ESC/Java2 consists of a

- parsing phase (syntax checks),
- typechecking phase (type and usage checks),
- static checking phase (reasoning to find potential bugs) - runs a behind-the-scenes prover called Simplify

Parsing and typechecking produce **cautions** or **errors**.

Static checking produces **warnings**.

The focus of ESC/Java2 is on static checking, but reports of bugs, unreported errors, confusing messages, documentation or behavior, and even just email about your application and degree of success are Very Welcome. [and Caution: this is still an alpha release]

Running ESC/Java2

- **Download the binary distribution from http://secure.ucd.ie/products/opensource/ESCJava2**

- **Untar the distribution and follow the instructions in README.release about setting environment variables.**

- **Run the tool by doing one of the following:**

  - **Run a script in the release: escjava2 or escj.bat**

  - **Run the tool directly with java -cp esctools2.jar escjava.Main, but then you need to be sure to provide values for the -simplify and -specs options.**

  - **Run a GUI version of the tool by double-clicking the release version of esctools2.jar**

  - **Run a GUI version of the tool by executing it with java -jar esctools2.jar (in which case you can add options).**

Supported platforms

ESC/Java2 is supported on

- **Linux**

- **MacOSX**

- **Cygwin on Windows**

- **Windows (but there are some environment issues still to be resolved)**

- **Solaris (in principle - we are not testing there)**

Note that the tool itself is relatively portable Java, but the underlying prover is a Modula-3 application that must be compiled and supplied for each platform.

Help with platform-dependence issues is welcome.

Environment

The application relies on the environment having

- **a Simplify executable (such as Simplify-1.5.4.macosx) for your platform, typically in the same directory as the application's jar file;**

- **the SIMPLIFY environment variable set to the name of the executable for this platform;**

- **a set of specifications for Java system files - by default these are bundled into the application jar file, but they are also in jmlspecs.jar.**

- **The scripts prefer that the variable ESCTOOLS_RELEASE be set to the directory containing the release.**

Command-line options

The items on the command-line are either options and their arguments or input entries. Some commonly used options (see the documentation for more):

- **-help** - prints a usage message

- **-quiet** - turns off informational messages (e.g. progress messages)

- **-nowarn** - turns off a warning

- **-classpath** - sets the path to find referenced classes [best if it contains '.']

- **-specs** - sets the path to library specification files

- **-simplify** - provides the path to the simplify executable

- **-f** - the argument is a file containing command-line arguments

- **-nocheck** - parse and typecheck but no verification

- **-routine** - restricts checking to a single routine

- **-eajava**, **-eajml** - enables checking of Java assertions

- **-counterexample** - gives detailed information about a warning

Input entries

The input entries on the command-line are those classes that are actually checked. Many other classes may be referenced for class definitions or specifications - these are found on the classpath (or sourcepath or specspath).

- **file names** - of java or specification files (relative to the current directory)

- **directories** - processes all java or specification files (relative to the current directory)

- **package** - (fully qualified name) - found on the classpath

- **class** - (fully qualified name) - found on the classpath

- **list** - (prefaced by **-list**) - a file containing input entries

Specification files

- **Specifications may be added directly to .java files**

- **Specifications may alternatively be added to specification files.**

  - **No method bodies**
  - **No field initializers**
  - **Recommended suffix: .refines-java**
  - **Recommend a refines annotation (see documentation)**
  - **Must also be on the classpath**

Specification file example

```
package java.lang;
import java.lang.reflect.*;
import java.io.InputStream;

public final class Class implements java.io.Serializable {

    private Class();

    /*@ also public normal_behavior
      @    ensures \result != null && !\result.equals("")
      @         && (* \result is the name of this class object *);
      @*/
    public /*@ pure @*/ String toString();

    ....
```

Bag demo

modular reasoning

ESC/Java2 reasons about every method individually. So in

```
class A{
  byte[] b;
  public void n() { b = new byte[20]; }
  public void m() { n();
                    b[0] = 2;
                    ...          }
```

ESC/Java2 warns that `b[0]` may be a null dereference here,

even though you can see that it won't be.

modular reasoning

To stop ESC/Java2 complaining: add a postcondition

```
class A{

 byte[] b;

 //@ ensures b != null && b.length = 20;

 public void n() { b = new byte[20]; }

 public void m() { n();

                   b[0] = 2;

                   ...          }
```

So: property of method that is relied on has to be made explicit.

Also: subclasses that override methods have to preserve these.

modular reasoning

Similarly, ESC/Java will complain about `b[0] = 2` **in**

```
class A{
  byte[] b;
  public void A() { b = new byte[20]; }
  public void m() { b[0] = 2;
                     ... }
```

Maybe you can see that this is a spurious warning, though this will be harder than in the previous example: you'll have to inspect *all* constructors and *all* methods.

modular reasoning

To stop ESC/Java2 complaining here: add an invariant

```
class A{
 byte[] b;
  //@ invariant b != null && b.length == 20;
        // or weaker property for b.length ?
 public void A() { b = new byte[20]; }
 public void m() { b[0] = 2;
                    ...  }
```

So again: properties you rely on have to be made explicit.

And again: subclasses have to preserve these properties.

assume

Alternative to stop ESC/Java2 complaining: add an assumption:

```
    ...
    //@ assume b != null && b.length > 0;
    b[0] = 2;
    ...
```

Especially useful during development, when you're still trying to discover hidden assumptions, or when ESC/Java2's reasoning power is too weak.

(`requires` can be understood as a form of `assume`.)

need for assignable clauses

```
class A{
 byte[] b;

 ...

 public void m() { ...
                    b = new byte[3];
                    //@ assert b[0] == 0; // ok!
                    o.n(...);
                    //@ assert b[0] == 0; // ok?
                    ...

 }
```

What does ESC/Java need to know about `o.n` to check the second assert ?

need for assignable clauses

```
class A{
 byte[] b;

 ...

 public void m() { ...
                   b = new byte[3];
                   //@ assert b[0] == 0; // ok!
                   o.n(b);
                   //@ assert b[0] == 0; // ok?
                   ...

 }
```

A detailed spec for `o.n` might give a postcondition saying that `b[0]` is still 0.

need for assignable clauses

```
class A{
 byte[] b;
 ...
 public void m() { ...
                    b = new byte[3];
                    //@ assert b[0] == 0; // ok!
                    o.n();
                    //@ assert b[0] == 0; // ok?
                    ...
 }
```

If the postcondition of `o.n` doesn't tell us `b` won't be not null – and can't be expected to – we need the `assignable` clause to tell us that `o.n` won't affect `b[0]`.

Declaring `o.n` as pure would solve the problem.

ESC/Java is not complete

ESC/Java may produce warnings about correct programs.

```
/*@ requires 0 < n;
  @ ensures \result ==
  @                 (\exists int x,y,z;
  @                   pow(x,n)+pow(y,n) == pow(z,n));
  @*/
public static boolean fermat(double n) {
  return (n==2);
}
```

Warning: *postcondition possibly not satisfied*
(Typically, the theorem prover times out in complicated cases.)

ESC/Java is not sound

ESC/Java may fail to produce warning about incorrect program.

```
public class Positive{

    private int n = 1;   //@ invariant n > 0;

    public void increase(){ n++; }
}
```

ESC/Java(2) produces no warning, but `increase` may break the invariant, namely if `n` is $2^{32} - 1$.

This can be fixed by improved model of Java arithmetic, but this does come at a price (both in specs and in code).

ESC/Java is not sound

More fundamental problem: sound modular verification for OO programs with invariants.

```
public class A{                      public class B{

  B b;

  int x;                                int y;

  //@ invariant x <= b.y;

  void decr_x(){                        void decr_y(){

    x--;  }                                   y--;  }

}                                    }
```

How can we know that invoking `decr_y` on some B won't break the invariant of some A, or some object whose invariant depends on a B object.

ESC/Java is not sound

```
public class A{                  public class B{

  B b;

  int x;                          int y;

  //@ invariant x <= b.y;

  void decr_x(){x++;}             void incr_y(){y++;}

}                                }

public class D{

  B b;

  void decr_y(){

     b.y--;  }

}
```

How can D know it might be breaking A's invariant?

Modularity problem

Modular verification for (open) OO programs with invariants is a big & fundamental problem. Most verification tools fail here. Root causes:

1. invariants talking about another object's fields

2. object modifying another object's field

3. possibility of **aliasing**

NB 1 & 2 are unavoidable, eg. think of an object modifying – or its invariant mentioning – the contents of an array field

Alias control and ownership might provide solutions, eg. universes by Peter Müller & co or explicit pack/unpack operations by Rustan Leino & co.
